

In JavaScript, the main difference is **type conversion**.

== — Loose Equality

== compares values **after JavaScript may convert their types**.

JavaScript

```
console.log(10 == "10");
```

Output:

```
true
```

Why? JavaScript converts **"10"** (string) to **10** (number) before comparing.

More examples:

JavaScript

```
10 == "10"      // true
true == 1       // true
false == 0      // true
"" == 0         // true
null == undefined // true
```

=== — Strict Equality

=== compares **both value AND data type**. No automatic type conversion is performed.

JavaScript

```
console.log(10 === "10");
```

Output:

```
false
```

Because:

```
10    → number
"10"  → string
```

More examples:

JavaScript

```
10 === "10"      // false
true === 1        // false
false === 0       // false
"" === 0          // false
null === undefined // false
```

Easy way to remember

Operator	Value	Type	Conversion
<code>==</code>	✓	✗	Yes
<code>===</code>	✓	✓	No

For testers, prefer `===`

When writing test automation or validations, `===` is **generally safer** because you don't want JavaScript silently converting your test data.

For example:

JavaScript

```
let actualAge = "18";

console.log(actualAge == 18);
```

Result:

true

That could hide a problem: your application returned a **string**, while you expected a **number**.

With:

JavaScript

```
console.log(actualAge === 18);
```

Result:

false

This immediately exposes the type mismatch.

Rule of thumb:

Use `===` by default. Use `==` only when you intentionally want JavaScript's type conversion.
